The Sampling Problem

This version of the document is dated 2023-07-16.

#### Peter Occil

This page is about a mathematical problem of **sampling a probability distribution with unknown parameters**. This problem can be described as sampling from a new distribution using an endless stream of random variates from an incompletely known distribution.

Suppose there is an endless stream of numbers, each generated at random and independently from each other, and as many numbers can be sampled from the stream as desired. Let  $(X_0, X_1, X_2, X_3, ...)$  be that endless stream, and call the numbers *input values*.

Let InDist be the probability distribution of these input values, and let  $\lambda$  be an unknown parameter that determines the distribution InDist, such as its expected value (or mean or "long-run average"). Suppose the problem is to produce a random variate with a distribution OutDist that depends on the unknown parameter  $\lambda$ . Then, of the algorithms in the section "Sampling Distributions Using Incomplete Information<sup>1</sup>":

- In Algorithm 1 (Jacob and Thiery 2015)<sup>2</sup>, InDist is arbitrary but must have a known minimum and maximum,  $\lambda$  is the expected value of InDist, and OutDist is non-negative and has an expected value of  $f(\lambda)$ .
- In Algorithm 2 (Duvignau 2015)<sup>3</sup>, InDist is a fair die with an unknown number of faces,  $\lambda$  is the number of faces, and OutDist is a specific distribution that depends on the number of faces.
- In Algorithm 3 (Lee et al. 2014)<sup>4</sup>, InDist is arbitrary,  $\lambda$  is the expected value of InDist, and OutDist is non-negative and has an expected value equal to the mean of f(X), where X is an input value taken.
- In Algorithm 4 (Jacob and Thiery 2015)<sup>5</sup>, InDist is arbitrary but must have a known minimum,  $\lambda$  is the expected value of InDist, and OutDist is non-negative and has an expected value of  $f(\lambda)$ .
- In Algorithm 5 (Akahira et al. 1992)<sup>6</sup>, InDist is Bernoulli,  $\lambda$  is the expected value of InDist, and OutDist has an expected value of  $f(\lambda)$ .
- In the **Bernoulli factory problem**<sup>7</sup> (a problem of turning biased coins to biased coins), InDist is Bernoulli,  $\lambda$  is the expected value of InDist, and OutDist is Bernoulli with an expected value of  $f(\lambda)$ .

In all cases given above, each input value is independent of everything else.

There are numerous other cases of interest that are not covered in the algorithms above. An example is the

case of **Algorithm 5** except InDist is any discrete distribution, not just Bernoulli. <sup>8</sup> An interesting topic is to answer the following: In which cases (and for which functions f) can the problem be solved...

- ...when the number of input values taken is finite with probability 1 (a sequential unbiased estimator)?
- ...when only a fixed number n of input values can be taken (a fixed-sample-size unbiased estimator)?
- ...using an algorithm that produces outputs whose expected value approaches  $f(\lambda)$  as more input values are taken (an asymptotically unbiased estimator)?

The answers to these questions will depend on—

- the allowed distributions for InDist,
- the allowed distributions for OutDist,
- which parameter  $\lambda$  is unknown,
- whether the inputs are independent, and
- whether outside randomness is allowed.

An additional question is to find lower bounds on the input/output ratio that an algorithm can achieve as the number of inputs taken increases (e.g., Nacu and Peres (2005, Question 2)<sup>9</sup>).

My interest on the problem is in the existence and construction of simple-to-implement algorithms that solve the *sampling problem* given here.

## 1 Results

It should be noted that many special cases of the sampling problem have been studied and resolved in academic papers and books.

The problem here is one of bringing all these results together in one place.

The following are examples of results for this problem.

- Suppose InDist takes on numbers from a finite set;  $\lambda$  is the expected value of InDist; and OutDist has an expected value of  $f(\lambda)$ .
  - A fixed-size unbiased estimator exists only if f is a polynomial of degree n or less, where n is the number of inputs taken (Lehmann (1983, for coin flips)<sup>10</sup>, Paninski (2003, proof of Proposition 8, more generally)<sup>11</sup>).
  - The existence of sequential unbiased estimators is claimed by Singh  $(1964)^{12}$ . But see Akahira et al.  $(1992)^{13}$ .
- Suppose InDist is Bernoulli,  $\lambda$  is the expected value of InDist, and OutDist is Bernoulli with an expected value of  $f(\lambda)$ .
  - Let D be the set of allowed values for  $\lambda$ . Thus, D is either the closed unit interval or a subset thereof.
  - A sequential unbiased estimator exists if and only if f is everywhere 0, everywhere 1, or continuous and polynomially bounded on D (Keane and O'Brien 1994)<sup>14</sup>.

<sup>&</sup>lt;sup>8</sup>Singh (1964, "Existence of unbiased estimates", Sankhyā A 26) claimed that an estimation algorithm with expected value  $f(\lambda)$  exists for a more general class of InDist distributions than the Bernoulli distribution, as long as there are polynomials that converge pointwise to f, and Bhandari and Bose (1990, "Existence of unbiased estimates in sequential binomial experiments", Sankhyā A 52) claimed necessary conditions for those algorithms. However, Akahira et al. (1992) questioned the claims of both papers, and the latter paper underwent a correction, which I haven't seen (Sankhyā A 55, 1993).

- Then a fixed-size unbiased estimator exists if and only if f is a polynomial of degree n with n+1 Bernstein coefficients in the closed unit interval, where n is the number of inputs taken (Goyal and Sigman 2012)<sup>15</sup>.
- Perhaps it is true that an asymptotically unbiased estimator exists if and only if there are polynomials  $p_1, p_2, ...$  that converge pointwise to f on D (that is, for each  $\lambda$  in D,  $p_n(\lambda)$  approaches  $f(\lambda)$  as n increases), and the polynomials' Bernstein coefficients lie in the closed unit interval (see also Singh (1964)<sup>16</sup>).

There are also two other results on the existence of fixed-sample and asymptotically unbiased estimators, but they are relatively hard to translate to this problem in a simple way: Liu and Brown (1993)<sup>17</sup>, Hirano and Porter (2012)<sup>18</sup>.
